### **INTRODUCTION**

Each year, the MSU potato breeding and genetics team conducts a series of variety trials to assess advanced potato selections from the Michigan State University and other potato breeding programs at the Montcalm Research Center (MRC). In 2015, we tested over 270 varieties and breeding lines in the replicated variety trials, plus over 170 lines in the National Chip Processing Trial (NCPT). The variety evaluation also includes disease testing in the scab nursery (Montcalm Research Center) and foliar and tuber late blight evaluation (Clarksville Research Center). The objectives of the evaluations are to identify superior varieties for fresh or chip-processing markets. The varieties were compared in groups according to market class, tuber type, skin color, and to the advancement in selection. We added a trial to focus on specialty market classes. Each season, total and marketable yields, specific gravity, tuber appearance, incidence of external and internal defects, chip color (from the field, 45°F (7.2°C) and 50°F (10°C) storage), as well as susceptibilities to common scab, late blight (foliar and tuber), and blackspot bruising are determined.

We would like to acknowledge the collaborative effort of the Michigan Potato Industry and research colleagues Bruce Sackett, Aaron Yoder and the MSU Potato Breeding Team (especially N. Garrity, M. Alhashany, S. Islam, F. Enciso, and N. Kirkwyland) for getting the research done.

### **PROCEDURE**

The field variety trials were conducted at the Montcalm Research Center in Entrican, MI. They were planted as randomized complete block designs with two to four replications. The plots were 23 feet (7 m) long and spacing between plants was 10 inches (25.4 cm). Inter-row spacing was 34 inches (86.4 cm). Supplemental irrigation was applied as needed. Nutrient, weed, disease and insect management were similar to recommendations used by the commercial operations. The field experiments were conducted in a four-year rotation on a sandy loam soil on the Comden ground that was in corn the previous 3 years and in potatoes four years previously.

The most advanced selections were tested in the Advanced chip and tablestock trials, representing selections at a stage after the preliminary trials. The other field trials

were the North Central, Russet, , Preliminary (chip-processors and tablestock), Preliminary Pigmented, Select Scab-Resistant MSZ-Lines, the NCPT and the early observational trials.

There were significant rains at the Montcalm Research Center in 2015 in the spring and the fall that flooding effected many plots, resulting in the loss of one or more replicate plots in various trials. The Preliminary Trials were some of the most effected, resulting in many single observation plots.

2015 was the fifth year of the National Chip Processing Trial (NCPT). The purpose of the trial is to evaluate early generation breeding lines from the US public breeding programs for their use in chip-processing. The NCPT has 9 trial locations (Northern sites: NY, MI, WI, ND, OR and Southern: NC, FL, CA, TX) in addition to a scab trial in MN. For 2016, the scab trial will be conducted in Wisconsin instead of Minnesota.

In each of these trials, the yield was graded into four size classes, incidence of external and internal defects in >3.25 in. (8.25 cm) diameter (or 10 oz. (283.5 g) for Russet types) potatoes were recorded. Samples were taken for specific gravity, chip-processing, disease tests and bruising tests. Chip quality was assessed on 25-tuber composite sample from four replications, taking two slices from each tuber. Chips were fried at 365°F (185°C) for 2 minutes 15 seconds or until fully cooked. The chip color was measured visually with the SFA 1-5 color chart and a Hunter Colorimeter using crushed chips. Tuber samples were also stored at 45°F (7.2°C) and 50°F (10°C) for chip-processing out of storage in January and April. Advanced selections are also placed in the MPIC B.F. Burt Cargill Commercial Demonstration Storage in Entrican, MI for monthly sampling. The lines in the agronomic trials were assessed for common scab resistance at the nursery at the Montcalm Research Center. There has been very strong scab disease pressure at the new Montcalm Scab Disease Nursery for five years now. The 2015 late blight trial was conducted at the Clarksville Research Center. Maturity ratings (1 early - 5 late) were taken for all variety trial plots in late August to differentiate early and late maturing lines. The simulated blackspot bruise results for average spots per tuber have also been incorporated into the summary sheets.

## RESULTS

### A. Advanced and Chip-Processing Trial (Table 1)

A summary of the 33 entries evaluated in the trial results is given in **Table 1**. Overall, the yields for the Advanced trial (131 days) were average to above. The check varieties for this trial were Snowden, Atlantic, and FL1879. The highest yielding lines were NY154, MSV313-2, A01143-3C, and MSR127-2. Vascular discoloration and hollow heart were the predominant internal defects. Specific gravity was high with most lines above 1.080. All chip-processing entries in the trial had excellent chip-processing quality out of the field, with an SFA score of 1.0. Many of the MSU breeding lines have good scab resistance, including: MSR127-2, MSW509-5, MSW474-1, MSW394-1, and

MSV383-B, MSR061-1 (late blight and PVY resistant), MSX398-2, MSX540-4 (late blight and PVY resistant), and MSW360-18 (PVY resistant) showed resistance to late blight at the CRC trials. The promising MSU chip-processing lines are MSR127-2, MSV313-2, MSX540-4, MSV507-056, MSW509-5, and MSW474-1. MSR061-1 is being named Saginaw Chipper and is finding production in the Pacific Northwest.

#### **B. North Central Regional Trial Entries (Table 2)**

The North Central Trial is conducted in a wide range of environments (6 regional locations) to provide adaptability data for the release of new varieties from Michigan, Minnesota, North Dakota, Wisconsin, and Canada. The trial was reformatted to focus on table potatoes. The russet potato lines were included in the Russet trial. Twenty entries were tested in Michigan in 2015. The results are presented in **Table 2**. The reference varieties for this trial were Red Norland, Dark Red Norland, Red LaSoda, and Yukon Gold. The best performing MSU lines in the trial were MSV093-1Y, MST386-1P, and MSS576-5SPL. MSV093-1Y is a yellow-flesh tablestock line with high yield potential as seen in this trial and in on-farm trials. MSV093-1Y produces a high percentage of oversize tubers that with no internal defects moderate scab tolerance. Certified seed for this line is being produced in the greenhouse for larger commercial testing. Other MSU lines that looked promising were MSS576-5SPL (late blight resistant), MST386-1P (purple skin, white flesh, scab resistant) and MSX540-4 (scab and PVY resistant chipper). There are some promising red/purple-skinned entries from Minnesota, North Dakota, and Wisconsin. Yukon Gold had the highest incidence of internal defects with 70% hollow heart.

#### **C. Russet Trial (Table 3)**

We continue to increase our russet breeding efforts to reflect the growing interest in russet types in Michigan. In 2015, 20 lines were evaluated after 120 days. The results are summarized in **Table 3**. The Russet trial includes entries from the North Central Regional Trial (NCR). Russet Norkotah and Silverton Russet were the reference varieties used in the trial. In general, the yields were average for many russet lines while Russet Norkotah had a low yield. The highest yielding line was W10074-8Rus, however, it had 50% hollow heart. Reveille Russet (ATX91137-1Rus) and W94111-1Rus (NCR) were also high yielding this year and in 2014. There was incidence of hollow heart in W10074-8Rus, AW07791-2Rus, CO5068-1Rus, and MSW496-1Rus. Specific gravity measurements were average with Russet Norkotah at 1.072. Off type and cull tubers were found in nearly all lines tested, with the highest being W9742-3Rus and ND7882b-7Russ (NCR). Scab resistance was common among the lines but susceptibility was observed in a number of the russet lines. No late blight resistance was observed in these lines at the CRC trial.

#### **D. Adaptation Trial (Table 4)**

The Adaptation Trial of the tablestock lines was harvested after 123 days and the results are summarized in **Table 4**. The majority of the lines evaluated in the Adaptation

Trial were tested in the Preliminary Trial the previous year. Three reference cultivars (Reba, Red Norland, and Superior) and 20 advanced breeding lines are reported in the tablestock trial. In general, the yields were average and internal defects were low, but some lines had hollow heart incidence (MSW121-5R and Reba). The highest yielding lines were MSV093-1, MSW121-5R, MSW259-5, and MSW151-05. MSV093-1Y is an attractive yellow-fleshed table selection high yield potential and moderate scab tolerance. The challenge remains to combine scab and late blight resistance together. The lines with scab tolerance were MSV093-1Y, MSS576-5SPL, MSW075-1, MST252-1Y, MSW324-1P, and McBride. Other promising late blight resistant lines were MSW121-5R, MSW151-05, MSS576-5SPL, MSV396-4Y and MSV235-2PY. Although the yield was low in this trial, MSV235-2PY is an attractive specialty line with purple skin and a yellow flesh for the small potato market and has excellent late blight resistance. This line is being tested by Tasteful Selections.

#### E. Preliminary Trials (Tables 5, 6, 7, and 8)

The Preliminary trials (chip, table, pigmented, scab resistant Z-selections) are the first replicated trials for evaluating new advanced selections from the MSU potato breeding program. The division of the trials was based upon pedigree assessment for chip-processing and tablestock utilization. In 2015, there were 159 lines trialed in the three Preliminary trials.

The chip-processing Preliminary Trial (**Table 5**) had 68 entries harvested after 123 days. Most lines chip-processed well from the field. Specific gravity values were average to high with Atlantic at 1.089 and Snowden at 1.084. Internal quality was predominantly hollow heart and vascular discoloration. Internal defects were lower than some years, with no hollow heart observed in Atlantic or Snowden. Promising MSU lines are MSX542-2, MST186-1Y, MSY008-3, MSX198-5, and MSX245-2Y combining yield, specific gravity, and chip quality. We continue to make progress selecting for chip-processing with scab resistance with 20 lines in the trial with scab ratings lower than Pike (1.5). We are also combining chip-processing quality and late blight resistance, with 9 selections demonstrating strong foliar late blight resistance, and 7 lines with moderate late blight resistance.

**Table 6** summarizes 69 tablestock entries evaluated in the Preliminary Tablestock Trial. Reba and Superior were the check varieties. This tablestock trial was harvested and evaluated after 120 days. MSY111-1, QSMSU08-04, Soroya, VC1009-1W/Y, MSX156-1Y and MSV502-5 were the highest yielding lines. MSY111-1 combines high yield potential with scab resistance and good internal quality. This trial also had a low incidence of internal defects. The number of tablestock selections with scab resistance (21) and late blight resistance (13) continue to increase.

The interest in the specialty market continues to increase. A new trial was created to test 22 entries in a targeted Preliminary Pigmented Trial (**Table 7**), which was harvested at 123 days. This trial evaluated breeding lines with unique skin and flesh colors. These lines have commercial agronomic performance and specialty

characteristics, as well as some scab and late blight resistances. The highest yielding lines were MSX517-3SPL (late blight resistant), Michigan Purple Sport I, MSZUNK-7, Dakota Ruby, and MSX507-1R (late blight resistant). Seven of the 22 lines also demonstrated scab resistance in the scab disease nursery.

A separate trial was conducted to evaluate select ‘MSZ’ chip-processing selections that were confirmed to be scab resistant over multiple years in on-farm testing under heavy scab disease pressure (**Table 8**). The trial had 47 entries, with Atlantic and Snowden as the reference varieties. The scab resistance in these clones have been evaluated on-farm. These selections combine agronomic performance, chip-processing quality, specific gravity, and scab resistance. There are over a dozen lines which have commercial promise and these lines were placed into tissue culture. The lines that are virus free are being seed increased. These include MSZ222-19 and three lines that also have PVY and late blight resistance: MSZ219-1, MSZ219-14 and MSZ219-46.

#### F. Potato Common Scab Evaluation (**Tables 9 and 10**)

Each year, a replicated field trial is conducted to assess resistance to common scab. The scab trial is now located at the Montcalm Research Center where high common scab disease pressure was observed in the previous five years. This location is being used for the early generation observational scab trial (479 lines) and the scab variety trial (230 lines).

We use a rating scale of 0-5 based upon a combined score for scab coverage and lesion severity. Usually examining one year's data does not indicate which varieties are resistant but it should begin to identify ones that can be classified as susceptible to scab. Our goal is to evaluate important advanced selections and varieties in the study at least three years to obtain a valid estimate of the level of resistance in each line. The 2012-2014 scab ratings are based upon the Montcalm Research Center site. **Table 9** categorizes many of the varieties and advanced selections tested in 2015 over a three-year period. The varieties and breeding lines are placed into six categories based upon scab infection level and lesion severity. A rating of 0 indicates zero scab infection. A score of 1.0 indicates a trace amount of infection. A moderate resistance (1.2 – 1.5) correlates with <10% infection. Scores of 4.0 or greater are found on lines with >50% infection and severe pitted lesions.

The check varieties Russet Norkotah, GoldRush, Red Norland, Yukon Gold, Onaway, Pike, Atlantic, and Snowden can be used as references (bolded in **Table 9**). The table is sorted in ascending order by 2015 scab rating. This year's results continue to indicate that we have been able to breed numerous lines with resistance to scab. A total of 71 lines, of the 230 tested, had a scab rating of 1.5 or lower in 2015. Most notable scab resistant MSU lines are MST386-1P, MSV092-2, MSX324-2R, MSX324-1P, MSU358-3, MSZ219-01, McBride, MSR061-1, MSR127-2, MSV301-2, MSV383-B, MSV179-1, MSW474-01, MSU379-1 and, MST252-1Y. The greater number of MSU lines in the resistant and moderately resistant categories indicates we are making progress in breeding more scab resistant lines for the chip-processing and tablestock markets.

Scab results from the disease nursery for the advanced selections are also found in the Trial Summaries (**Tables 1-8**).

There are also an increasing number of scab resistant lines that also have late blight resistance and PVY resistance such as MSR061-1, MSX540-4 and MSZ219-14. We also continue to conduct early generation scab screening on selections in the breeding program beginning after two years of selection. Of the 479 early generation selections that were evaluated, over 267 had scab resistance (scab rating of  $\leq 1.5$ ) (**Table 10**).

#### H. Late Blight Trial (**Tables 11 and 12**)

In 2015, the late blight trial was planted at the Clarksville Research Center. Over 250 entries were planted in early June for late blight evaluation. These include lines tested in a replicated manner from the agronomic variety trial (153 lines) and 114 entries in the early generation observation plots. The trials were inoculated in early August with the US-23 genotype of *P. infestans*. Late blight infection was identified in the plots within 2 weeks after inoculation. The plots were evaluated 1-2 times per week over a 50-day period following inoculation. In 2015 the replicated variety trial 62 lines had late blight resistance, while 41 lines in the early generation observation plots had late blight resistance. These were from various late blight resistance sources in the pedigree of the selections (LBR9, Malinche, Kenya Baraka, Monserrat, Torridon, Stirling, NY121, Tollocan, B0718-3, Chapsa, *S. bulbocastanum*, *S. microdontum*, Muruta, Muriranrara, Enfula, Perkoz, Basadre, etc.). Most notable lines with late blight resistance include MSR061-1, MSX540-4, MSZ219-01, MSZ219-14, MSS576-05SPL, MSW485-2, MSW121-2R and MSV235-2PY. **Tables 11 and 12** list the foliar late blight disease ratings for select lines based on percent disease over time (RAUDPC; Relative Area Under the Disease Progress Curve). Please note that because of the lower level of infection, our cutoff for resistance was a very low RAUDPC score so we did not include false positives.

#### I. Blackspot Bruise Susceptibility (**Table 13**)

Evaluations of advanced seedlings and new varieties for their susceptibility to blackspot bruising are also important in the variety evaluation program. Based upon the results collected over the past years, the non-bruised check sample has been removed from our bruise assessment. A composite bruise sample of each line in the trials consisted of 25 tubers (a composite of 4 replications) from each line, collected at the time of grading. The 25 tuber sample was held in 50°F (10°C) storage overnight and then was placed in a hexagon plywood drum and tumbled 10 times to provide a simulated bruise. The samples were peeled in an abrasive peeler in October and individual tubers were assessed for the number of blackspot bruises on each potato. These data are shown in **Table 13**. The bruise data are represented in two ways: percentage of bruise free potatoes and average number of bruises per tuber. A high percentage of bruise-free potatoes is the desired goal; however, the numbers of blackspot bruises per potato is also important. Cultivars which show blackspot incidence greater than Atlantic are approaching the bruise-susceptible rating. In addition, the data is grouped by trial, since

the bruise levels can vary between trials. In 2015 the bruise levels were higher than previous years. There are many lines with lower blackspot bruise potential across the trials. Some of our advanced selections are similar to Atlantic and Snowden in their level of bruising.

#### **J. National Chip Processing Trial (NCPT) data available on-line**

The United States Potato Board (USPB)-funded National Chip Processing Trial (NCPT) is an effort to synergize the strengths of the public breeding programs in the U.S. to identify improved chip-processing varieties for the industry. Cooperating breeding programs include the USDA (Idaho and Maryland) and land grant universities (Colorado, Maine, Michigan, Minnesota, North Carolina, North Dakota, New York, Oregon, Wisconsin and Texas). The coordinated breeding effort includes early stage evaluation of key traits (yield, specific gravity, chip color, chip defects and shape) from coordinated trials in 11 locations. Since the inception of the trial in 2010, over 900 different potato entries, including reference varieties, have been evaluated. The data for all the lines tested are summarized on a searchable, centralized database housed at North Carolina State University. More than 30 promising new breeding lines from the trials have been fast-tracked for larger-scale commercial trials and processor evaluation. The NCPT is also a feeder for the national USPB/Snack Food Association trials. The data from all trials are available in a searchable, on-line database (<https://potatoes.ncsu.edu/ncptsrch.php>). We are using the NCPT trials to more effectively identify promising new selections. These are MSV301-2, MSV358-3, MSW485-2, MSW509-5, MSV030-4 and MSX540-4. Minituber production and/or commercial seed have been produced of these lines and will be tested in Michigan in 2015.

SCAB DISEASE RATING: MSU Scab Nursery plot rating of 0-5; 0: No Infection; 1: Low Infection <5%, no pitted lesions; 3: Intermediate >20%, some pitted lesions (Susceptible, as commonly seen on Atlantic); 5: Highly Susceptible, >75% coverage and severe pitted lesions.

N = Number of replications.

\*2-Year Average.

\* Twenty to twenty-five A-size tuber samples were collected at harvest, held at 50 F at least 12 hours, and placed in a six-sided plywood drum and rotated ten times to produce simulated bruising. Samples were abrasive-peeled and scored 10/28-29/2015. The table is presented in ascending order of average number of spots per tuber.
